**Diagrams**

At constant speed, looking at the input shaft, and clockwise rotation

At constant rotational speed with regard to the input shaft and rotation in clockwise direction.

By connecting the two signals A and B, an output signal arises whose period durations  $tx1 \dots tx4$  have varying lengths.

The differences are determined:

- by the pulse/pause ratio tolerance of the individual channels
- by the tolerance in the 90° phase shift between A and B
- by the frequency

The times  $tx1 \dots tx4$  ideally have to amount to 1/4 of the particular period duration T. The typical output frequency of the encoder is defined so that the max. time  $tx$  is smaller than  $1.5 \times T/4$ .

Polpairs	Number of poles	e, f, g, h, i, k	$\alpha$
2	4	30°	180°
3	6	20°	120°
4	8	15°	90°
6	12	10°	60°
8	16	7.5°	45°

The angle information is related to a mechanical shaft rotation. Flank precision of the signals R, S, T  $\pm 1^\circ$ .
